Don’t Do This

Jimmy Angelakos
Senior Solutions Architect

PGConf.DE 2023-06-27
What is this talk?

- Not all-inclusive
- There is literally nothing you cannot mess up
- Misconceptions
- Confusing things
- Common but impactful mistakes
We’ll be looking at

• Bad SQL
• Improper data types
• Improper feature usage
• Performance considerations
• Security considerations
NOT IN

Doesn’t work the way you expect!

- As in: `SELECT ... WHERE ... NOT IN (SELECT ...)`
- SQL is not Python or Ruby!
  - `SELECT a FROM tab1 WHERE a NOT IN (1, null);` returns NO rows!
  - `SELECT a FROM tab1 WHERE a NOT IN (SELECT b FROM tab2);
    same, if any b is NULL`
- Why is this bad even if no NULLs?
  - Query planning / optimization
  - Subplan instead of anti-join
What to do instead?

• Anti-join

• SELECT col
  FROM tab1
  WHERE NOT EXISTS
    (SELECT col
     FROM tab2
     WHERE tab1.col = tab2.col);
NOT IN

Or:

• SELECT col
  FROM tab1
  LEFT JOIN tab2 USING (col)
  WHERE tab2.col IS NULL;

• NOT IN is OK, if you know there are no NULLs
  – e.g. excluding constants: NOT IN (1,3,5,7,11)
BETWEEN

Especially with TIMESTAMPs

• BETWEEN (1 AND 100) is inclusive (closed interval)
• When is this bad?

```
SELECT sum(amount)
FROM transactions
WHERE transaction_timestamp
BETWEEN ('2023-02-05 00:00' AND '2023-02-06 00:00');
```
Be explicit instead, and use:

```sql
SELECT sum(amount)
FROM transactions
WHERE transaction_timestamp >= '2023-02-05 00:00'
AND transaction_timestamp < '2023-02-06 00:00';
```
Using upper case in identifiers

For table or column names

- Postgres makes everything lower case unless you double quote it
- `CREATE TABLE Plerp (…);`
  `CREATE TABLE "Quux" (…);`
  - Creates a table named `plerp` and one named `Quux`
  - `TABLE Plerp;` works – `TABLE "Plerp";` fails
  - `TABLE Quux;` fails – `TABLE "Quux";` works
  - Same with column names
- For pretty column names: `SELECT col AS "Pretty Name" FROM plerp;`
Improper data types
TIMESTAMP (WITHOUT TIME ZONE)

a.k.a. naïve timestamps

• Stores a date and time with no time zone information
  – Arithmetic between timestamps entered at different time zones is meaningless and gives wrong results

• TIMESTAMPTZ (TIMESTAMP WITH TIME ZONE) stores a moment in time
  – Arithmetic works correctly
  – Displays in your time zone, but can display it AT TIME ZONE

• Don’t use TIMESTAMP to store UTC because the DB doesn’t know it’s UTC
TIMETZ

Or TIME WITH TIME ZONE has questionable usefulness

• Only there for SQL compliance
  – Time zones in the real world have little meaning without dates
  – Offset can vary with Daylight Savings
  – Not possible to do arithmetic across DST boundaries

• Use TIMESTAMPTZ instead
CURRENT_TIME
Is TIMETZ. Instead use:

- CURRENT_TIMESTAMP or now() for a TIMESTAMPTZ
- LOCALTIMESTAMP for a TIMESTAMP
- CURRENT_DATE for a DATE
- LOCALTIME for a TIME
CHAR(n) / VARCHAR(n)

Padded with whitespace up to length n

- Padding spaces are ignored when comparing
  - But not for pattern matching with LIKE & regular expressions!
- Actually not stored as fixed-width field!
  - Can waste space storing irrelevant spaces
  - Performance-wise, spend extra time stripping spaces
  - Index created for CHAR(n) may not work with a TEXT parameter

- company_name VARCHAR(50) → Peterson’s and Sons and Friends Bits & Parts Limited
- To restrict length, just enforce CHECK constraint
- Bottom line: just use TEXT (VARCHAR)
MONEY

Get away

• Fixed-point
  − Doesn’t handle fractions of a cent, etc. – rounding may be off!
• Doesn’t store currency type, assumes server LC_MONETARY
• Accepts garbage input:

  # SELECT ',123,456,,7,8.1,0,9'::MONEY;
  money
  money
  ----------------
  £12,345,678.11
  (1 row)

• Just use NUMERIC and store currency in another column
SERIAL

Used to be useful shorthand but now more trouble than it’s worth

- Non SQL Standard
- Permissions for sequence created by SERIAL need to be managed separately from the table
- CREATE TABLE ... LIKE will use the same sequence!
- Use identity columns instead:

  CREATE TABLE tab (id BIGINT GENERATED BY DEFAULT AS IDENTITY PRIMARY KEY, content TEXT);

- With an identity column, you don’t need to know the name of the sequence: ALTER TABLE tab ALTER COLUMN id RESTART WITH 1000;
- BUT: if application depends on a serial sequence with no gaps (e.g. for receipt numbers), generate that in the application
Improper feature usage
**SQL_ASCII**

*Is not a database encoding*

- No encoding conversion or validation!
  - Byte values **0-127** interpreted as ASCII
  - Byte values **128-255** uninterpreted
- Setting behaves differently from other character sets
- Can end up storing a mixture of encodings
  - And no way to recover original strings
CREATE RULE

RULEs are not the same as TRIGGERs

• Rules don’t simply apply conditional logic
  – They rewrite queries to modify or add extra queries
  – All non-trivial rules will probably have unintended side-effects
  – Non SQL Standard

• If you are not creating writable VIEWs, use TRIGGERs instead

• Look for Depesz’s exhaustive blog post on rules:
  https://www.depesz.com/2010/06/15/to-rule-or-not-to-rule-that-is-the-question
Table inheritance

- Seemed like a good idea before ORMs…

- \texttt{e.g. CREATE TABLE \texttt{events} (id \texttt{BIGINT}, \ldots \texttt{many columns} \ldots); CREATE TABLE \texttt{meetings} (scheduled\_time \texttt{TIMESTAMPTZ}) INHERITS \texttt{events};}

- Was used to implement partitioning ($< \text{PG 10}$)

- Incompatible with declarative partitioning ($\geq \text{PG 10}$):
  - One cannot inherit from a partitioned table
  - One cannot add inheritance to a partitioned table
How to undo table inheritance

• You can replace table inheritance with foreign key relations
• Create a new table to hold the data, and add the FK column:

```
CREATE TABLE new_meetings LIKE meetings;
ALTER TABLE new_meetings ADD item_id BIGINT;
```

• Copy data from old table into new one (may take a long time):

```
INSERT INTO new_meetings
SELECT *, id FROM meetings;
```

• Create required constraints, indexes, triggers etc. for new_meetings
CREATE TABLE (...) INHERITS ...

How to undo table inheritance (continued)

• **Very dirty hack** (if your table is huge) - create the FK but do not validate it now to avoid the full table scan:

```sql
ALTER TABLE new_meetings
CONSTRAINT event_id_fk
FOREIGN KEY (event_id)
REFERENCES events (id)
NOT VALID;
```

• If doing this on a live system, create a trigger to replicate changes coming into `meetings` also into `new_meetings`

• Normally one should not touch `pg_catalog` directly, but we can

```sql
UPDATE pg_constraint SET convalidated = true WHERE conname = 'event_id_fk';
```

as we are confident that data in FK column is valid (as exact copy of the original table)
How to undo table inheritance (continued)

• Inside a transaction, perform all the DDL at once:

```sql
DO $$
BEGIN
    ALTER TABLE meetings RENAME TO old_meetings;
    ALTER TABLE new_meetings RENAME TO meetings;
    DROP TABLE old_meetings;
    -- IMPORTANT: Create trigger to INSERT/UPDATE/DELETE items in
    -- events as they get changed in meetings - it's easy as now
    -- we have the FK.
    COMMIT;
END $$ LANGUAGE plpgsql;
```
Partitioning by multiple keys

Is not partitioning on multiple levels

- Be careful!

- `CREATE TABLE` transactions ( ... , location_code TEXT, tstamp TIMESTAMPTZ) PARTITION BY RANGE (tstamp, location_code);

- `CREATE TABLE` transactions_2023_02_a PARTITION OF transactions FOR VALUES FROM ('2023-02-01', 'AAA') TO ('2023-03-01', 'BAA');

- `CREATE TABLE` transactions_2023_02_b PARTITION OF transactions FOR VALUES FROM ('2023-02-01', 'BAA') TO ('2023-03-01', 'BZZ');

  ERROR: partition "transactions_2023_02_b" would overlap partition "transactions_2023_02_a"
Partitioning by multiple keys

Subpartitioning is what you actually need

• CREATE TABLE transactions (…, location_code TEXT, tstamp TIMESTAMPTZ) PARTITION BY RANGE (tstamp);

• CREATE TABLE transactions_2023_02 PARTITION OF transactions FOR VALUES FROM ('2023-02-01') TO ('2023-03-01') PARTITION BY HASH (location_code);

• CREATE TABLE transactions_2023_02_p1 PARTITION OF transactions_2023_02 FOR VALUES WITH (MODULUS 4, REMAINDER 0);
Performance considerations
Number of connections

Don’t overload your server for no reason

• `max_connections = 5000`

• Every client connection spawns a separate backend process
  - IPC via semaphores & shared memory
  - Risk: CPU context switching

• Accessing the same objects from multiple connections may incur many Lightweight Locks (LWLocks or “latches”)
  - Lock becomes heavily contended, lots of lockers slow each other down
  - You may be making your data hotter for no reason
  - No queuing, more or less random
Number of connections

Mitigation strategy

• Pre-PG 13: **Snapshot contention**
  - Each transaction has an MVCC snapshot – even if idle!

• Contention often caused by too much concurrency
  - Insert a connection pooler (e.g. **PgBouncer**) between application and DB
  - Allow fewer connections into the DB, make the rest queue for their turn
  - “Throttle” or introduce latency on the application side, to save your server performance
    • Sounds counter-intuitive!
    • Doesn’t necessarily slow anything down – queries may execute faster!
High transaction rate

Just because you can, doesn’t mean you should

• Postgres assigns an identifier to each transaction
  – Unsigned 32-bit int (4.2B values)
  – Circular space, with a visibility horizon
• XID wraparound: you try to read a very old tuple that is > 2.1B XIDs in the past
• Very heavy OLTP workloads can go through 2.1B transactions in a short time
  – For you, that’s the future! (invisible)
  – Freezing: Flag tuple as “frozen” which is known to always be in the past
• Need to make sure FREEZE happens before XID wraparound
High transaction rate

What can you do?

• Can batching help?
  - Does application really need to commit everything atomically?
  - Batch size 1000 will have 1/1000th the burn rate

• Increase effectiveness of autovacuum
  - More efficient FREEZE
Turning off autovacuum
a.k.a. the MVCC maintenance operation. Yeah, don’t.

• Removes dead tuples, freezes tuples (among other things)

• Has overhead
  - Scans tables & indexes
  - Needs, obtains, and waits for locks
  - Has limited capacity by default

• People are concerned about overhead
  - Alternative is worse! You can’t avoid \texttt{VACUUM} in Postgres (yet).
  - You can outrun it (and then you’ll need \texttt{VACUUM FULL})
Turning off autovacuum

For most production workloads, defaults are too low

- Make it work harder to avoid problems
- Increase potency via:
  - `maintenance_work_mem` (1GB is good)
  - `autovacuum_max_workers`
  - `autovacuum_vacuum_cost_delay / autovacuum_vacuum_cost_limit`
Explicit locking
a.k.a. heavyweight locks

- Table-level (e.g. SHARE) or row-level (e.g. FOR UPDATE)
- Conflict with other lock modes (e.g. ACCESS EXCLUSIVE with ROW EXCLUSIVE)
- Block read/write access totally leading to waits
- Disastrous for performance
  - Unless your application is exquisitely crafted
  - Hint: it isn’t
Explicit locking

Lock contention: waiting for explicit locks

• Avoid explicit locking!

• Use SSI (Serializable Snapshot Isolation, SERIALIZABLE isolation level)

• Make application tolerant
  - Allow it to fail and retry

• Slightly reduced concurrency, but:
  - No blocking, no explicit locks needed (SIReadLocks, rw-conflicts)
  - Best performance choice for some application types
Security considerations
psql --w or --password

Request password before attempting connection

• It will ask for a password even if the server doesn’t require one
• Unnecessary: `psql` will always ask for a password if required by server
• Insecure: You may think you’re logging in with a password
  – But the server may be in `trust` mode and letting you in anyhow
  – Also, you may be entering the wrong password and still getting in
  – From a different client, you may get a surprise!
listen_addresses = "*"

Listening for connections from clients

- There’s a reason the default is 'localhost' (only TCP/IP loopback)
- Make sure you only enable the interfaces and networks which you actually want to have access to the database server
- e.g. Internet connection on one network & private network on another interface
- Don’t advertise your presence: 3,600,000 MySQL/MariaDB servers (port 3306) found exposed on the Internet in May 20
Host-Based Authentication

• Called that for a reason, i.e. configuring with `host` … like:

```
host mydb myuser 10.10.10.10/32 md5
```

• `trust` with `host(ssl)` is a Very Bad Idea
  - Even for `local` e.g. improper user can connect to the DB
  - Postgres might be fine, but other software on the same server could be compromised

• Default to giving access only where strictly necessary (better safe...)
Database owned by superuser

Do you really need to?

• Use superuser only for management of global objects
  – Such as users
  – Good security practice
• Superuser bypasses a lot of checks
• (Bad) code that’s normally harmless could be exploited in harmful way with superuser access
• Try to restrict database ownership to standard users
Thank you!
